## **MAX 240 IGG FOOD** **SENSITIVITY**

MaxGen Labs and US BioTek Laboratories' proprietary ELISA analyses are designed to assay specific IgG (subclasses 1, 2, 3, 4) antibodies. The classification of 0 to IV denotes the level of IgG antibodies detected through spectrophotometric analysis. The antigens on the panel are subject to change without prior notice. Reference ranges are updated periodically. This test was developed and its performance characteristics determined by US BioTek Laboratories, LLC, 16020 Linden Ave N, Shoreline, WA 98133, USA. Test methodology has not been cleared or approved by the U.S. Food and Drug Administration.

## What are Food Sensitivities

Food sensitivities are inflammatory responses of the immune system triggered by food allergens. Unlike food allergies, food sensitivity symptoms often occur hours or even days after exposure, making it difficult to pinpoint the specific offending food(s). This delayed reaction causes the majority of the 12 million people estimated to suffer from food sensitivities to be unaware and blame things like aging for their chronic symptoms. The foods identified within this report may streamline identifying triggering foods.

IgG is an antibody that can activate the pro-inflammatory complement system (complement cascade) associated with chronic inflammatory conditions. High levels of IgG (Moderate / High / Very High) overload receptors and drive the inflammatory reaction, while low levels of IgG (Very Low / Low) indicate tolerance.

IgG testing is the most commonly performed food sensitivity testing, and foods that are only high in IgG can often be safely re-introduced after a few months of abstinence. Retesting later can help determine higher priority foods for long-term avoidance.

## Symptoms of Food Sensitivities

Brain Fog  
Bloating  
Weight Gain  
Mood Swings  
Joint Pain/Inflammation  
Constipation  
Diarrhea  
Bronchitis  
Crohn's disease  
Eczema  
Migraines  
GI distress  
Stomach pain  
Acne  
ADD/ADHD  
Autism  
Sinus issues  
Depression

## Food Sensitivities vs Food Allergies

Food allergies can cause an immediate histamine reaction within minutes to hours of ingesting food. Food allergy is an immune system reaction. Many of these reactions can be life-threatening. These allergies are typically diagnosed at a younger age. Common food allergies include dairy (cow's milk), eggs, tree nuts, wheat, peanut, soy, and seafood. Food allergy affects an estimated 8% of children under age five and up to 4% of adults. While there's no cure, some children outgrow their food allergies as they get older, per the Mayo Clinic.

When you have a true food allergy, your immune system identifies a specific food or a substance in food as something causing harm. Your immune system then triggers cells to release an immunoglobulin E (IgE) antibody to neutralize the allergy-causing food or food substance (the allergen).

Food sensitivities involve different immunoglobulin and do not produce life-threatening reactions. The symptoms typically associated with food sensitivities are longer lasting and slower to present, making them hard to identify in many cases.
